METHOD AND APPARATUS USING A CIRCUIT MODEL TO EVALUATE CELL/BATTERY PARAMETERS

ABSTRACT OF THE DISCLOSURE

Testing apparatus senses the time-varying electrical response of an electrochemical cell/battery to time-varying electrical excitation. The cell/battery may, or may not, be in service. Computation circuitry responsive to the time-varying electrical response evaluates elements of а unique circuit model representation of the cell/battery. Performance parameters and physical parameters are computed from these element values. Computed performance parameters include, but are not limited to, "total storage capacity", "absolute stored charge", "state-of-charge", "absolute cranking current", "fully charged cranking current", and "state-of-health". Computed physical parameters include, but are not limited to, "exchange current", "maximum exchange current", "charge transfer conductance", "maximum charge transfer conductance", "double layer capacitance", and "maximum double layer capacitance". Computed parameters are either displayed to the user, employed to initiate an alarm, or used to control a process such as charging the cell/battery.
